

FACTOIDS

Carlos M. Martinez-Cagnazzo

FIRST Miami 2010

A Little About Me...

- I have been involved in incident response since 2005
 - So i have suffered all of the problems I'm going to talk about today
- This work is still a work in progress so any:
 - Criticism
 - Comments
 - In fact, anything you have to say about it
- is very welcome!

The Problem

- *"How (this or that network activity) is seen from other networks?"*
 - Many times, when responding to computer security incidents this question pops up
- Other people (researchers, software developers) often face similar problems
 - How to obtain datasets of network activity from other groups?

The Problem (II)

- How do we "solve" it today?
 - Public domain datasets
 - CAIDA
 - Others
 - Limited, many times outdated
 - Try to generate data ourselves
 - Limited view, can be "expensive"
 - Get data from other groups
 - A trust relationship must be in place
 - There are regulations that must be taken into account

Datasets

- Research and CSIRT groups build datasets that can be of great value to other groups
 - Data collected by sensors (honeypots, IDSs)
- However, multiple issues make the exchange of these datasets difficult
 - Trust
 - Do you trust your peer to share data?
 - Local and regional regulations
 - Personal data protection laws
 - Information Security policies within each organization

Trust - How do We Manage It Today?

- We do what we are doing here today at this FIRST event. We meet and get to know each other...
- We establish some framework
 - MoUs (memorandum of understanding)
 - NDAs (non-disclosure agreements)
- We then filter the data we decide to share
- Problems:
 - Not very flexible, once an MoU is in place it's very hard to modify
 - Language barriers, different laws make compatibility difficult

Is There a Better Way?

- What if?
 - Many groups (CSIRTs) exposed at least a *sanitized* view of their sensor data for other groups to use?
 - Sanitization
 - *Hide what you don't want other people to see*
 - Typically
 - Internal IPs / hostnames
- Then...
 - Incident responders / researchers would then be able to tap on these sources of data
 - Downloading only the data they need, maybe using a specialized query language

A Better Way...

1. Mutually prove identities

2. Intantiate policies

Policy

CSIRT #1

CSIRT #2

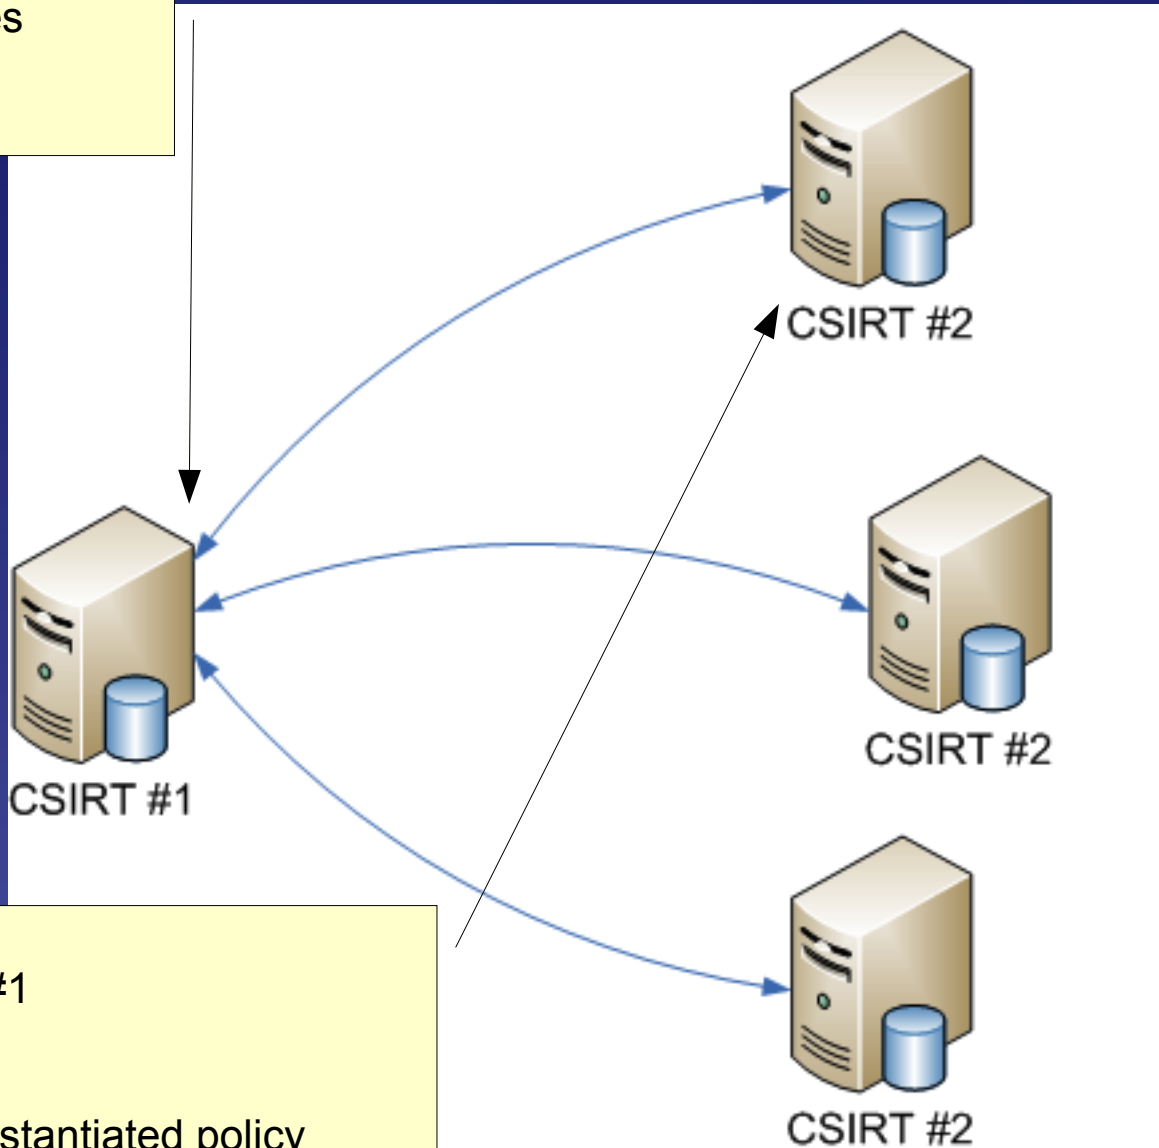

CSIRT #2

CSIRT #2

3. CSIRT #2 transmit
uses an API exposed by #1

4. CSIRT #1 outputs data
filtered according to the instantiated policy

What Do We Need to Make this Possible?

- Data models
 - We need to represent sensor data in an uniform way
- Automatic sanitization
 - The data each group sends to another must be automatically sanitized (no human intervention)
- Query languages / APIs
 - Efficient transport
- A *directory* of available information
 - Which group has which kind of information?

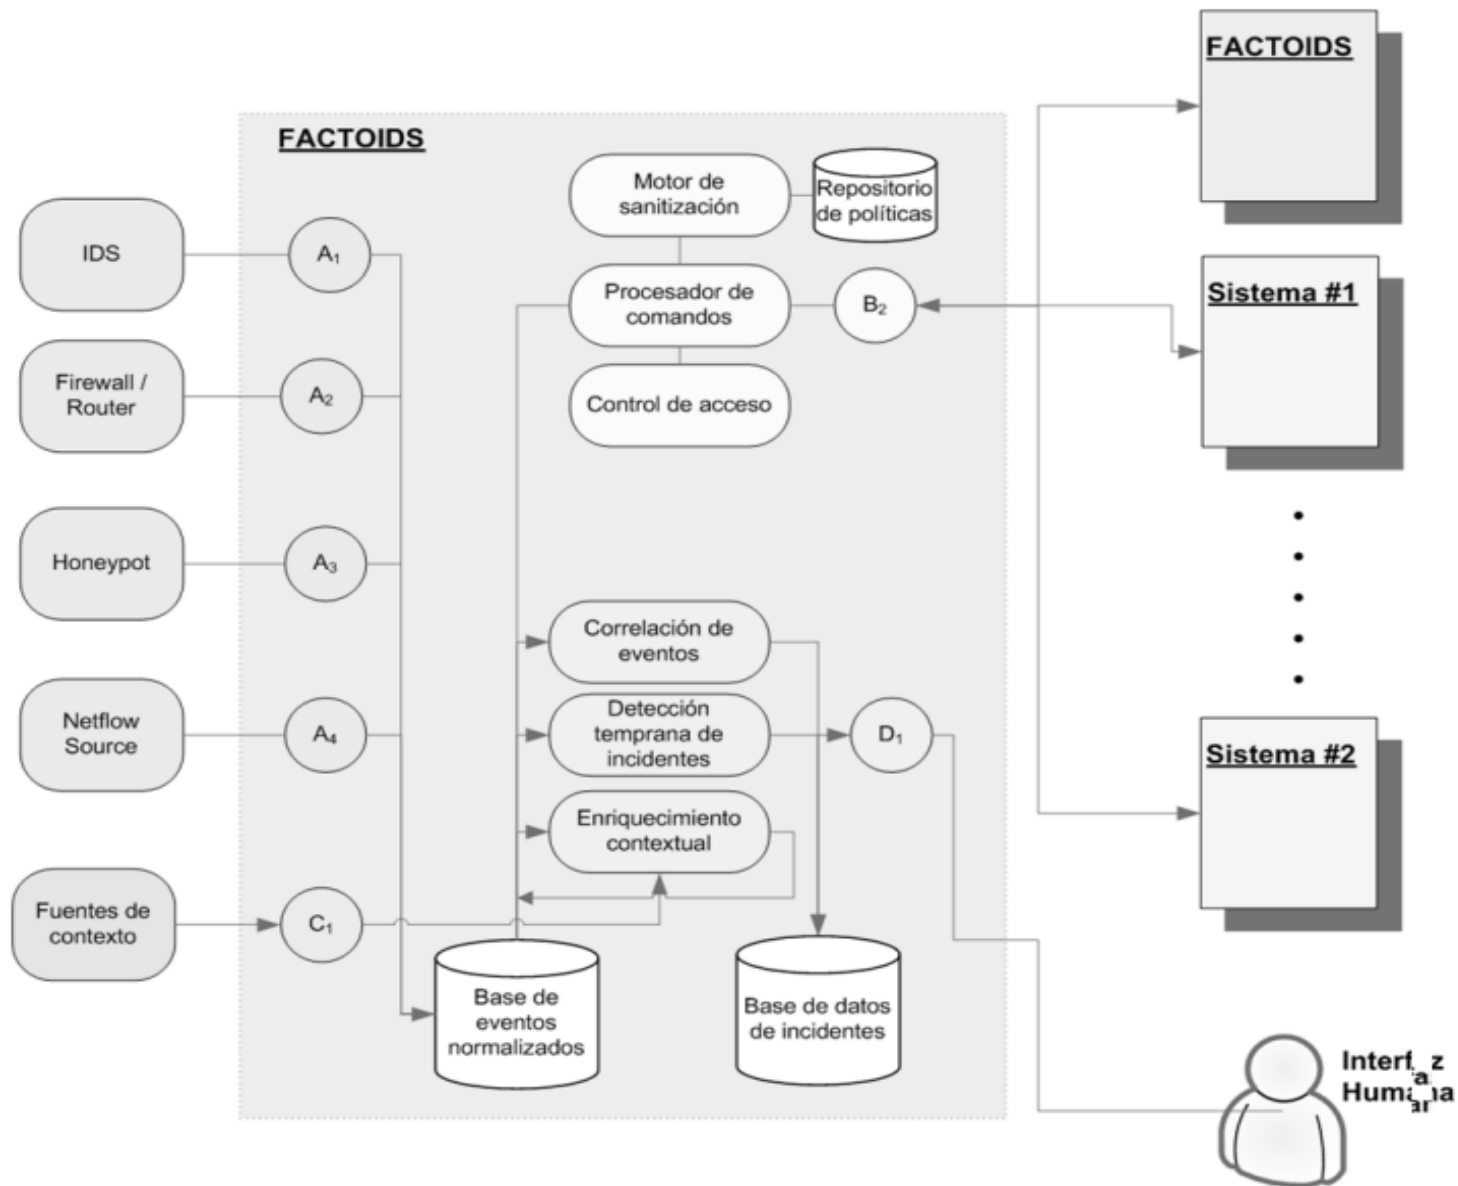

FACTOIDS – Vision

- FACTOIDS: "*Models and Tools for Analysis and Secure Exchange of Sensor-Collected Data*"
- Vision:
 - Efficient creation and management of *trust relationships* between groups who need to share security event data
 - Have control over which data is shared with whom
 - Improve transport efficiency of large sets of related data (*datasets*) regarding security events
 - Transport only what is needed

FACTOIDS – Potential Uses

- Real-time data exchange when responding to incidents
- Current and "real" datasets for research purposes
- *Law enforcement agencies*
- Software developers

FACTOIDS – Architecture

Dataset Transport

- Normalization
 - The same event is almost always detected by several sensors
 - We must normalize our dataset to avoid duplicates
- Size
 - A honeynet, firewall or IDS can by itself generate large-size datasets
 - Instead of moving huge files back and forth, why not expose an API and/or a query language?

Sanitization Policies

- Sanitization: output data filtered according to a policy
- Techniques:
 - Non-property preserving
 - "Black Marker"
 - Property preserving
 - Depending on the type of data

Current College(s): Law School
Current Major(s): Law

The fight for ██████████ can draw some stark battle lines. It's often painted as an "██████ versus ████████" battle, with ██████████ in the role of "██████" and everyone else cast as "██████". So where does that leave ██████████ people with ██████████ who believe in ██████████? Afraid of being branded the enemy, yet deeply committed to ██████████, they're left wandering in ██████████.

This conflict can lead most ██████████ to keep their ██████████ hidden-- making it impossible for them to bring their ██████████, ██████████ and ██████████ to the struggle for ██████████.

██████████ is a resource guide for people with ██████████ who are tired of ██████████, who are ready to dig through ██████████ and figure out ██████████ and ██████████. Complete with ██████████, ██████████ and ██████████, ██████████ gives its readers ██████████ and instead ██████████.

Conclusions

- We believe there is a need for a set of models and techniques to enable more data sharing among groups
- Many stand to benefit from a more open data sharing environment
- Roadblocks need to be overcome
 - Comply with regulations
 - Ensure groups control what information gets shared

FACTOIDS – Next Steps

- Implement a sub-set of the system
 - Representing events as XML documents using IODEF (RFC 5070)
 - Implement a proof-of-concept sanitization engine and policy repository
 - Implement event loading from our honeypot network

Thank you for your patience!
